Exploratory factor analysis for ordinal categorical data

- Install required packages
- Factor analysis
 - Simulate categorical data based on continuous variables
 - Factor analysis for ordered categorical data
- Factor scores
- Visualize loadings
- Determine number of factors
- Detach (automatically) loaded packages (if possible)
- Get the article source from GitHub

Install required packages

`GPArotation` (<http://cran.r-project.org/package=GPArotation>), `mvtnorm` (<http://cran.r-project.org/package=mvtnorm>),
`polycor` (<http://cran.r-project.org/package=polycor>), `psych` (<http://cran.r-project.org/package=psych>)

```
wants <- c("GPArotation", "mvtnorm", "polycor", "psych")
has <- wants %in% rownames(installed.packages())
if(any(!has)) install.packages(wants[!has])
```

Factor analysis

Simulate categorical data based on continuous variables

First, let's simulate 200 observations from 6 variables, coming from 2 orthogonal factors. I'll take a couple of intermediate steps and start with multivariate normal continuous data that I later dichotomize. That way, we can compare Pearson correlations with polychoric correlations, and compare factor loadings from continuous data with that from dichotomous data and the true loadings.

```
set.seed(123)
N <- 200          # number of observations
P <- 6           # number of variables
Q <- 2           # number of factors

# true P x Q loading matrix -> variable-factor correlations
Lambda <- matrix(c(0.7,-0.4, 0.8,0, -0.2,0.9, -0.3,0.4, 0.3,0.7, -0.8,0.1),
                 nrow=P, ncol=Q, byrow=TRUE)
```

Now simulate the actual data from the model $x = \Lambda f + e$, with x being the observed variable values of a person, Λ the true loadings matrix, f the latent factor score, and e iid, mean 0, normal errors.

```
# factor scores (uncorrelated factors)
library(mvtnorm)      # for rmvnorm()
FF <- rmvnorm(N, mean=c(5, 15), sigma=diag(Q))

# matrix with iid, mean 0, normal errors
E <- rmvnorm(N, rep(0, P), diag(P))
X <- FF %*% t(Lambda) + E # matrix with variable values
dfX <- data.frame(X)     # data also as a data frame
```

Now let's categorize the data. We'll keep the data in two formats: as a data frame with ordered factors, and as a numeric matrix. `hetcor()` from package `polycor` gives us the polychoric correlation matrix we'll later use for the FA.

```
# categorize variables into a list of ordered factors
l0rd <- lapply(dfX, function(x) {
  cut(x, breaks=quantile(x), include.lowest=TRUE,
      ordered=TRUE, labels=LETTERS[1:4]) })
df0rd <- data.frame(l0rd) # combine list into a data frame
ordNum <- data.matrix(df0rd) # categorized data as a numeric matrix
```

Factor analysis for ordered categorical data

Use the polychoric correlation matrix to do a regular FA.

```
library(polycor)      # for hetcor()
pc <- hetcor(df0rd, ML=TRUE) # polychoric corr matrix
```

```
library(psych)
faPC <- fa(r=pc$correlations, nfactors=2, n.obs=N, rotate="varimax")
faPC$loadings
```

Loadings:

```
      MR2  MR1
X1  0.546 -0.196
X2  0.607
X3 -0.173  0.842
X4 -0.197  0.311
X5  0.336  0.537
X6 -0.619
```

```
              MR2  MR1
SS loadings  1.231 1.133
Proportion Var 0.205 0.189
Cumulative Var 0.205 0.394
```

It is possible to skip the step of calculating the polychoric correlation matrix, and directly use `fa.poly()` from package `psych`, which does the same thing in the end. This function accepts the raw dichotomous data as a numeric matrix.

```
# polychoric FA
faPCdirect <- fa.poly(ordNum, nfactors=2, rotate="varimax")
```

```
faPCdirect$fa$loadings      # Loadings are the same as above ...
```

Loadings:

```
      MR2  MR1
X1  0.546 -0.196
X2  0.605
X3 -0.174  0.841
X4 -0.198  0.311
X5  0.336  0.538
X6 -0.621
```

```
              MR2  MR1
SS loadings  1.231 1.133
Proportion Var 0.205 0.189
Cumulative Var 0.205 0.394
```

Factor scores

For factor scores, look at package `ltm` which has a `factor.scores()` function specifically for polytomous outcome data. An example is provided on this page (<http://eur.academia.edu/DimitrisRizopoulos/Teaching>) -> "Factor Scores - Ability Estimates".

Visualize loadings

You can visualize the loadings from the factor analysis using `factor.plot()` and `fa.diagram()`, both from package `psych`. For some reason, `factor.plot()` accepts only the `$fa` component of the result from `fa.poly()`, not the full object.

```
factor.plot(faPCdirect$fa, cut=0.5)
```

plot of chunk rerMultFApoly01

```
fa.diagram(faPCdirect)
```

Factor Analysis

plot of chunk rerMultFApoly01

Determine number of factors

Parallel analysis and a "very simple structure" analysis provide help in selecting the number of factors. Again, package `psych` has the required functions. `vss()` takes the polychoric correlation matrix as an argument.

```
fap <- fa.parallel.poly(ordNum) # parallel analysis for dichotomous data
```

Eigen values of tetrachoric/polychoric matrix

plot of chunk rerMultFApoly02

```
fap
```

```
Call: fa.parallel.poly(x = ordNum)
```

Parallel analysis suggests that the number of factors = 2 and the number of components = 2

Eigen Values of

	Original factors	Simulated data	Original components	simulated data
1	1.23	0.76	1.92	1.30
2	0.62	0.19	1.53	1.15

```
vss(pc$correlations, n.obs=N, rotate="varimax") # very simple structure
```

Very Simple Structure

plot of chunk rerMultFApoly03

```
Very Simple Structure
```

```
Call: VSS(x = x, n = n, rotate = rotate, diagonal = diagonal, fm = fm,  
n.obs = n.obs, plot = plot, title = title)
```

```
VSS complexity 1 achieves a maximum of 0.61 with 6 factors
```

```
VSS complexity 2 achieves a maximum of 0.76 with 6 factors
```

```
The Velicer MAP criterion achieves a minimum of NA with 1 factors
```

```
Velicer MAP
```

```
[1] 0.08 0.11 0.22 0.40 1.00 NA
```

```
Very Simple Structure Complexity 1
```

```
[1] 0.41 0.58 0.60 0.60 0.56 0.61
```

```
Very Simple Structure Complexity 2
```

```
[1] 0.00 0.69 0.73 0.69 0.75 0.76
```

Detach (automatically) loaded packages (if possible)

```
try(detach(package:GPArotation))
try(detach(package:psych))
try(detach(package:polycor))
try(detach(package:sfsmisc))
try(detach(package:mvtnorm))
```

(based on an answer I wrote on CrossValidated)
